

Project title :Implementation Client Script & UI Policy

Phase 1:Brainstorming and Ideation phase

1. Client-Side Configuration and Form Automation

The implementation of Client Scripts and UI Policies in ServiceNow plays an important role in improving the functionality, usability, and efficiency of forms. Client Scripts are used to perform client-side actions such as validating user inputs, setting field values, and displaying messages, while UI Policies are used to dynamically control field visibility, mandatory status, and read-only properties. By implementing these features effectively, the system can provide a more interactive and user-friendly experience, reduce manual errors, and ensure that the required information is captured accurately. This project focuses on implementing Client Scripts and UI Policies to enhance form behavior and improve the overall incident management process.

2. Concept and Purpose

In ServiceNow, managing data entry manually on IT Service Management (ITSM) forms often leads to discrepancies, delayed routing, and missed Service Level Agreements (SLAs). The core idea of this project is to implement robust, automated, client-side data validation on the Incident Form using UI Policies and Client Scripts. By enforcing dynamic behavioral rules directly at the user interface level, this configuration ensures high data integrity before records hit the database.

3. Key Brainstormed Capabilities

* High-Impact Automation: Dynamically alter the form behavior whenever an Incident is classified as a high-impact event.

- * Preventive Form Validation: Stop invalid or incomplete data submission at the client end to reduce server-side rejection overhead.
- * Contextual Control Enforcement: Restrict modifications based on how the form is accessed (Form view vs. List view).
- * Conditional Reversibility: Ensure that if criteria change, form configurations dynamically revert to their original state instantly.
